Problem Statement

Introduction

Nestlé Purina is one of the top manufactures of pet food in the United States. The Flagstaff, AZ plant produces about 1,000 tons of pet food each day. When the food is done cooking it contains 35% moisture content. Therefore, all of the food produced needs to be properly dried to meet the 11.5% moisture content requirement. This requirement was set forth to reduce the risk of mold growth due to the build-up of condensation in the bags while cooling. To dry the food, the Flagstaff plant has five steam powered dryers, each responsible for about 20%. However, dryer three is not running as efficient as the other dryers. Dryer 3, shown in Figure 1, should be capable of producing 200 tons per day, but has recently been producing only 150 tons per day, while still using the same amount of energy as the other 4 dryers.

Figure 1 – Dryer 3

After the product enters the dryer, it is passed through 4 sections. The first 3 sections are responsible for removing moisture from the product, and the fourth section is responsible for cooling the product. Each section has its own dedicated air flow, temperature control, and steam coils. The steam coils are used to heat up the air that moves through each section, as hot air can contain much more moisture than cool air.

The lack of productivity is largely due to the condensation in the steam used for drying the pet food. Because of the large scale of production, this degree of inefficiency costs our client a large amount of money in terms of unmade product. Our goal is to increase the efficiency and throughput of dryer 3 for Nestlé Purina.

Objectives

Below is a table of the objectives and measurement basis we have come up with for the implementation of this project to increase the efficiency of dryer 3.

Objectives	Basis for Measurement	Units
Inexpensive	Implementation costs	\$
Production output	Weight of product	Tons
Moisture content	Amount of water	%
Efficiency	Energy used	BTU/ ton
Condensation	Weight of water in the steam	Kg water/ kg steam

Table 1 -	Objectives
-----------	------------

Constraints

Overall, we were given three constraints to meet during the project. The first constraint is that the moisture content must be less than 11.5% to avoid the growth of mold in the product. The second constraint is that the payback period should be less than eight years to justify the cost of the project. The last constraint is there must be no condensation in the steam coils so heat transfer can occur optimally.

By developing a criteria tree shown in Figure 2, an approach can be made on how to go about addressing the problem of dryer 3 but still keep in mind the objectives and constraints given.

Criteria Tree

The criterion was split into three different categories: costs, moisture control, and production. The most important criteria to consider with the designs of the dryer are the amount of money that will be spent. The total cost includes the payback period which is the amount of time that it takes for the money spent to pay for itself. The next category is moisture control. This category was then split into the amount of water that is still in the product, and the amount of condensation that is in the steam. The final category is the total production of the dryer. This includes the total amount of product that can be pushed through the dryer in a span of an hour and how much power we need to push that much product through. We also need to compare the new efficiency of the dryer to the efficiency of the old dryers.

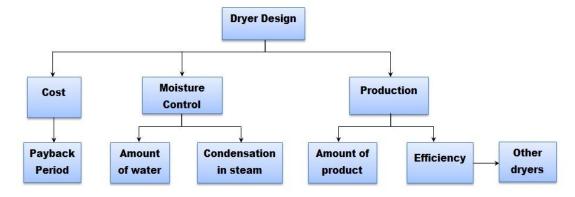

Figure 2 – Criteria Tree

To better understand the process of the dryer and where to perform our engineering analysis, a functional diagram of dryer 3 was made. This is shown in Figure 4 below. The dryer runs on steam in conjunction with an air circulation system. The plant produces its own steam in a natural gas boiler. This steam is then pumped at approximately 100 psi to the dryer unit. In the dryer, steam is continually pumped through steam coils. The air circulation system blows air over the steam coils to heat the air to around 280 degrees Fahrenheit. Hot air has a larger capacity to remove moisture than air at a lower temperature. This air passes through the moist product and removes moisture from it. After this, the air is re-heated and passed through the product twice more. The product enters the fourth and final section of the dryer where it is cooled to about 100 degrees Fahrenheit before it is sent to further processing.

Quality Function Deployment

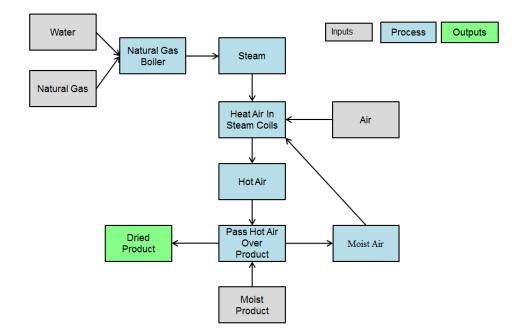

Figure 3 – Function Diagram

A quality function deployment table, Figure 5, compares customer needs to engineering needs. It relates overall design to reasonable engineering specifications. From the figure, cost relates to all of the customer requirements. To make the dryer more efficient for allowing more product throughput, the cost will increase. To be more durable, there will be more materials used or longer lasting parts which will be more expensive. This also affects the overall weight of the dryer and energy reduction. Ideally, the output should be 10% more efficient than the dryers already in use which gives us the engineering targets. The house of quality refers to how the engineering requirements relate to each other. There is a positive correlation (+) between cost and energy reduction. This means that by increasing the cost, the energy reduction should be larger. By increasing the energy reduction, the output tonnage decreases. This is a negative correlation (-).

		+ + + + Engineering Requirements					
		Weight	Cost	Payback Period	Energy reduction	Tonnage	
nts	Inexpensive	x	x	x	x		
Customer Requirements	Allow for more product throughput		x	x	x	x	
Customer	Durable	x	x	x			
	Units	ton	\$	<u>yrs</u>	%	ton	
		100	250k	8	10	20/day	
			En	gineering	Targets		

Figure 4 – Quality Function with House of Quality

Concept Generation

Before we were able to select a design to move forward with, we first had to generate a multitude of concepts to choose from. We accomplished this by breaking the concept generation section into multiple stages. These stages are: defining the problem, defining the system, brainstorming, using Osborn's Checklist to expand these ideas, and then refining the ideas to prepare for concept selection. Through our previous work, we were able to interpret our client's need and generate a concrete problem statement. We determined that the problem was: Dryer 3 at Nestle Purina uses significantly more energy than the other four dryers to extract moisture from the product.

The next step in our concept generation and selection process was to define the system and understand it as completely as possible. We were able to meet with Chad Girvin, the processing maintenance team leader at the Nestle Purina plant in Flagstaff. Chad was able to provide us detail about the system that one would only learn by spending years with a specific system.

We realize now that the drying process at Nestle Purina is very complicated, but we were able to take note of the most critical pieces of the system and its operation. The first step of the drying process is bringing the product to the front of the dryer from the exit of the extruder, or product cooker. This is done with a vacuum conveyance system. Each dryer has a dedicated blower that creates a vacuum to pull the product to the dryer. The vacuum conveyance system is a very important part of the drying process as it provides about ¹/₄ of the moisture removal as a fraction of the entire drying process.

Once the product is pulled through the vacuum conveyance system, it is deposited onto the dryer bed by an oscillating belt. This belt speed can be controlled, and helps to control the product depth and uniformity. The belt speed also affects the time the product spends in the dryer. After the product enters the dryer, it is passed through 4 sections of the dryer. The first 3 sections are responsible for removing moisture from the product, and the fourth section is responsible for cooling the product. Each section has its own dedicated air flow, temperature control, and steam coils. The steam coils are used to heat up the air that moves through each section, as hot air can contain much more moisture than cool air. In addition to using Chad Girvin as a resource for information, we were also able to use Nestle Purina's process monitoring system called iFix to gather information on the system. The computer interface with this system is shown in figures 1 and 2. Figure 1 depicts all of the relevant information for dryer 3, which is the focus of our project. iFix provides a large amount of data, and we focused on a few key details to determine the relative efficiency of dryer 3. We used dryer 1 as a reference; data for dryer 1 can be found in figure 2.

The percentages displayed along the dryer bed represent the percentage of dryer steam usage as a comparison to the dryer capacity. Figures 1 and 2 show that dryer 3 is running at near capacity, while dryer 1 is running at approximately 70% capacity. To quantify the dryer steam usage, we were able to access the steam flow rate for each dryer, in terms of pounds of steam per hour, or pph. The steam flow rate for dryer 3 was 4009.3 pph at the time of measurement and the steam flow rate for dryer 1 was 3414.6 pph.

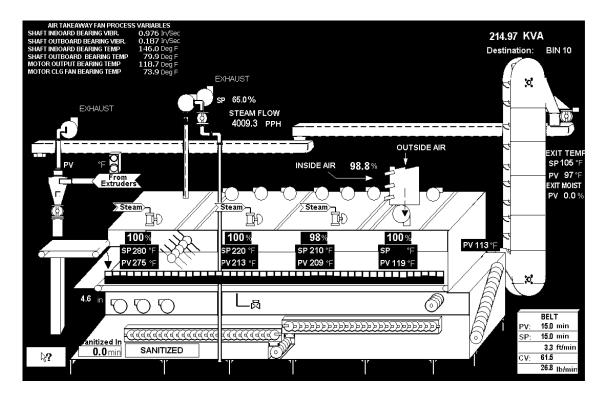

Figure 5 - Dryer 3 Source: Nestle Purina Process Monitoring System

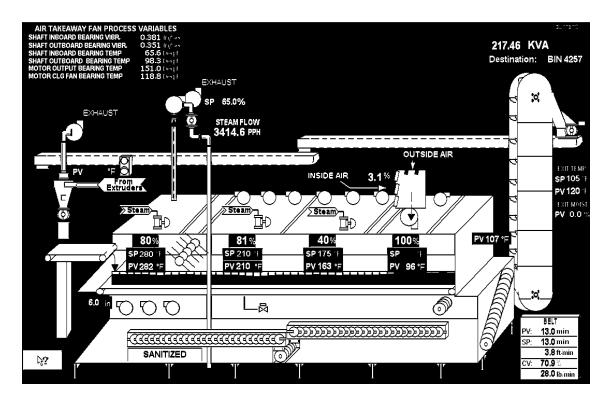

Figure 6 - Dryer 1 Source: Nestle Purina Process Monitoring System

We also needed a way to quantify the product throughput through the dryer. iFix provides the product bed depth, and the dryer bed operates at a constant speed, so we decided to define a dryer efficiency index as inches of product depth per steam flow rate in pounds per hour. The indexes were small, so we made them easier to read by multiplying by 1000. The efficiency index of dryer 3 was determined to be 1.147 and the efficiency index of dryer 1 was determined to be 1.7516. The percent difference between the efficiency index of dryer 3 and 1 was 34.7%, with dryer 1 displaying a significantly higher efficiency rating. We used all of this information to aide our brainstorming, concept generation, and concept selection.

In the brainstorming stage, we came up with any and all solution ideas to achieve better efficiency in dryer 3 compared to the other 4 dryers. There were no bad ideas or negative feedback in this stage, as one idea can lead to another. Some ideas range from outright buying a new boiler from off the shelf to redesigning the existing boiler to changing the insulation and fuel for the boiler itself. Initial research and price quotes for these solutions range upward of half a million dollars so a careful inspection of these ideas are necessary.

To further generate concepts from the brainstorming stage, we used Osborn's Checklist shown in Table 1. This method allows one to expand the list of ideas by asking how to adapt, modify, magnify, minify, substitute, rearrange, and combine. By following this procedure, we obtain many more concepts; some good and some unreasonable. For example, by taking the original concept of insulation, we can increase the amount of insulation around main pipes, decrease insulation around other pipes, use different insulation material, or a combination of these designs. Then, to refine the list for top, viable concepts, we used a weighted criteria tree with a decision matrix.

Rebuild Steam Traps	Buy new steam traps (Industrial Automation Services)	Eliminate need for steam traps	More Steam Traps	Less, more effective steam traps	New steam trap design	Rework how dryer uses steam	
Insulate	Performance contracting insulators, new insulation for steam travel	Insulate entire steam travel distance	More insulation	Different insulation			
Boiler	Look at efficiency of a new boiler	Modify boiler piping	More boiler production	Less boiler use	Look into boiler shut down and start up data	Put small boiler in for dryers	<- less distance steam has to travel
Fuel(Boiler)	Natural gas, coal, No. 6 Fuel	Different boiler fuel source	Run at full capacity for maximum efficiency	Reduce to one boiler from two	Different fuel		Steam system changes
Steam properties	Look at other plants operating conditions	Change steam properties (Latent heat, pressure, density)	Ramp up steam energy	Minimize steam energy	Change steam for natural gas	Max combination of properties to maximize efficiency	
Dryer Fuel	Natural gas conversion	Look into alternative fuels	Max out steam energy transfer	Maximize efficiency to minimize fuel	New steam coil design	Rearrange heat transfer system	
Steam system	Minimize transportation of steam	Eliminate steam	Increase steam capacity to maximize efficiency	Minimize steam use in plant	Substitute out new fuel for dryers	Move boilers	
Product	Look at other plants operational conditions	Only run certain product through dryer 3	Maximize bed depth	Less output from dryer	Run product multiple times through dryer	Change bed arrangement	
Dryer Air Flow	Analyze air flow	Maximize heat transfer	Minimize fan speed	Increase air flow for dryer air	Pull in fresh air in between sections	Dry air between sections	
Dryer size	Buy new dryer	Maximize product bed depth	Increase bed surface to decrease depth	Decrease bed surface area to maximize air flow	New machine to dry product		

 Table 2 - Osborn's Checklist

Concept Selection

Since there are three criteria, the team needs to determine the overall importance for the criteria. So the team can make a decision matrix for the concepts. Therefore the Analytical Hierarchy Process is applied to determine the overall importance.

The scale is from 1 to 9. Number "1" represents two criteria are equally important. Number "5" represents one criterion is strongly more important than the other criterion. Number "9" represents one criterion is extremely more important than the other criterion.

In the Pairwise Comparison Matrix, the team determines that the moisture control is moderately more important that the cost. The production is strongly more important than the cost and moisture control. So the values are putted in the matrix. The total value is the sum of the values in each column. The value of each criterion in the matrix is divided by the total value in that column. The normalized values are shown in the Normalized Importance and Overall Importance table. By taking the average of the normalized value in the row, the team gets the overall importance for the criteria. The overall importance of the cost is 0.211. The overall importance of moisture control is 0.102. The overall importance of production is 0.686.

Judgment	Equally		Moderately		Strongly		Very		Extremely
of	important		more		more		strongly		more
Important			important		important		more		important
							important

	Cost	Moisture	Production	Overall
				Importance
Cost	0.158	0.333	0.143	0.211
Moisture Control	0.053	0.111	0.143	0.102
Production	0.789	0.556	0.714	0.686

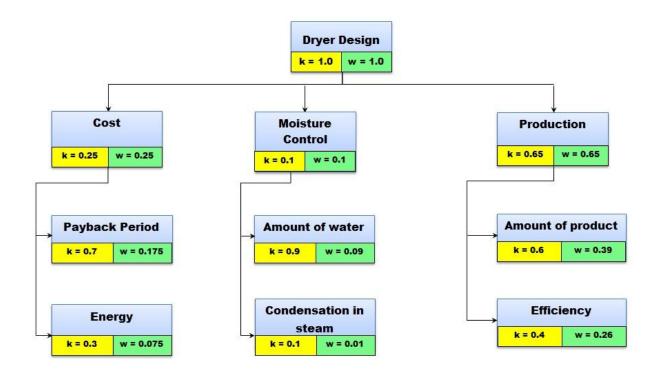

Figure 7 - Weighted Criteria Tree

Each criterion was given a relative weight of how important they are to each other for each category. Cost was determined by our client to be of twenty-five percent importance, while moisture control was ten percent importance and production was sixty-five percent. In each of the three categories; cost, moisture control, and production were broken down into their sub criteria and ranked on importance of each other. Under cost, the payback period was rated as an overall seventy percent while the energy to run the dryer was ranked as thirty percent important. The same technique was applied to the other categories. After each of the criteria received their specific weight, they were then multiplied by the overall weight for that category. This allowed for an overall ranking of how important each of the criteria were to the overall design.

We used a clearly defined strategy to generate concepts to solve this problem, and also to select which concepts we would be pursuing in our engineering analysis. This strategy was to clearly define our problem, clearly define our system, brainstorm ideas, and then use Osborn's checklist to expand and refine these raw ideas. Then, we used a weighted criteria tree as well as an analytic hierarchy process to determine our best solution options from our refined idea list. As a result, we were able to conclude that our best three solution options are: Analyzing the steam

characteristics, analyzing the air flow inside the dryers, and re-designing the dryer air flow. These three ideas will be our basis when we begin to look into the engineering analysis section of our design process.

Engineering Analysis

Current System

After the product enters the dryer, it is passed through 4 sections of the dryer. Figure 1 shows a schematic of how the dryer operates. The first 3 sections are responsible for removing moisture from the product, and the fourth section is responsible for cooling the product. Each section has its own dedicated air flow, temperature control, and steam coils. The steam coils are used to heat up the air that moves through each section, as hot air can contain much more moisture than cool air.

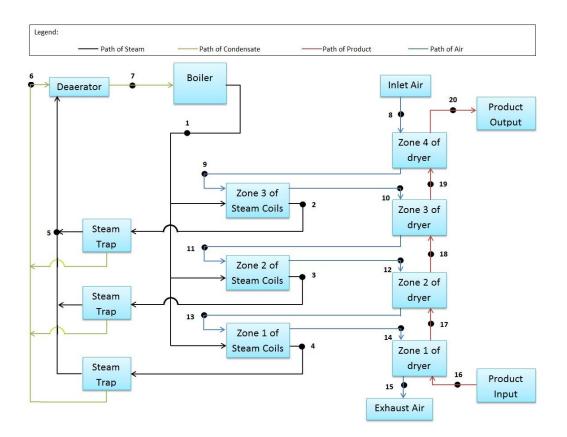

Figure 8 – Overall schematic of how the dryer works with points of interests for thermodynamic analysis.

Analysis of Steam

In order to ensure the system is operating correctly, the operation of the subcomponents must be analyzed. The analysis conducted below is for an individual steam coil. Each steam coil acts as a heat exchanger where an input of steam heats up air in a cross flow pattern. The energy balance for the control volume is as follows:

$$\frac{dE}{dt} = Q_{in} - W_{out} + \sum \dot{m}i \left[h_i + \frac{v_i^2}{2} + gz_i \right] - \sum \dot{m}i \left[h_e + \frac{v_e^2}{2} + gz_e \right]$$
(1)

Where:

 Q_{in} Heat in

h

- *W_{out}* Work done
- *m* Mass flow rate

Enthalpy

- V Velocity of fluid
- g Gravitational constant
- z Elevation

The above equation is simplified with the assumptions that kinetic and potential energy can be neglected. Furthermore no work is done by the system; however loss of energy must be accounted for. Thus equation 1 can be rewritten as:

$$E_{Loss} = \dot{m}_{steam}(h_1 - h_2) + \dot{m}_{air}(h_3 - h_4) + \dot{m}_{vapor}(h_3 - h_4)$$
(2)

In order to solve the above equation, the properties of the steam and drying air at every node must be known. All of the properties for the steam are known, however the mass flow rate for the air is not determined by the facilities software. Therefore the mass flow rate of air is estimated by using the known power of the motors that move the air. The following equation relates power to mass flowrate:

$$P = \frac{\frac{mgh}{33000}}{\eta\eta_e} \tag{3}$$

Where:	'n	Mass flow rate	
`	g	Gravitational constant	
	h	Total head	
	η	Efficiency of the motor	

 η_e Mechanical energy (converting electricity)

Since the values for the amount of power for the motor is known (10 horsepower), we can determine the overall expected mass flow rate once we get the data about the overall efficiency of the motor, the mechanical energy, and the total head caused by the velocity and pipe frictions. Once we have calculated the mass flow rate, we need to determine how much of the mass is made up of water vapor and how much is made up of air. By using the equation for moisture content it allows us to determine the ratio of vapor to air:

$$\omega = \frac{m_{vapor}}{m_{air}} \tag{4}$$

Equation 2 will be utilized to determine the operational condition of each independent heat exchanger of the dryer. Those values will be compared to each of the heat exchangers in another dryer found in the plant. This will allow us to determine how differently dryer three is operating from dryer one.

The only data that we have collected so far is listed in Table 1, where each point was defined earlier in Figure 1. This data in combination with the data from the other dryers will allow us to determine if there is a discrepancy with the heat exchangers.

Point	Description	Property	Others
1	Stream inlet	T = 273F	should be saturated
		P = 50psi	steam
2	zone 3 steam outlet	T = 230F	
3	zone 2 steam outlet	No Data Collected	
4	zone1 steam outlet	No Data Collected	
5	steam trap outlet	T = 100F

			content
20	zone 4 (inlet)/ dryer	T = 100F	9% moisture content
	outlet		

Table 6 – Collected thermodynamic properties for each point defined in Figure 1.

After our analysis, we are going to determine the best way to fix whatever is causing the problem. To determine the best way of fixing the problem, we are going to perform a cost analysis. This will allow us to determine exactly how much the increase in cost will be, and how long it will take for the increase in productivity to pay for the increase in costs.

Natural Gas Conversion

Another idea that we are looking into is converting the steam dryer over to a dryer that runs on natural gas. This would replace the use of steam to this dryer therefore eliminating the issue of the problematic drying. Instead of using the three different steam coils and steam traps, all of that would be replaced by a natural gas burner which heats the air directly drying the product as a result. Figure 2 shows a schematic of how the natural gas dryer operates.

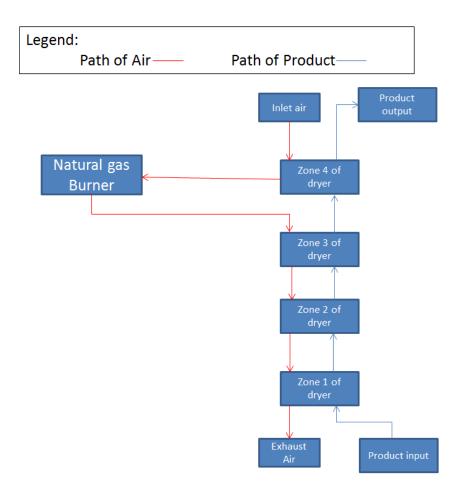

Figure 9 - Schematic of the natural gas dryer.

After the product enters the dryer, it is passed through 4 sections of the dryer. Air enters the fourth zone to cool the product down. Then the air will be heated up by the natural gas burner. After air being heated up, it enters the other 3 sections of the dryer which will remove the moisture from the product.

$$Q_{Combustion} = \dot{m}_{air} * (h_1 - h_2) + \dot{m}_{vapor}(h_1 - h_2) + E_{Loss}$$
(5)

$$Q_{Combustion} = \dot{m}_{gas} * \Delta H_{comb} * \eta \tag{6}$$

Where:hEnthalpy Q_{Comb} HeatWWork done \dot{m} Mass flow rate

 ΔH_{comb} Heat of combustion

η Burner Efficiency

The energy released by the burning of natural gas is given in equation 6, which is used in equation 5 to find the energy lost to entropy generation. The mass flow rates are determined either using the flow to power relationship given in equation 3 or are measured.

These dryers have a much higher efficiency than the steam dryers, reducing the overall amount of cost for fuel while greatly increasing the amount of product that can go through the dryer at any given time. However, this conversion is a very significant cost so it ultimately would depend on whether our client would want to go that route. If they do decide to go that route, the payback period is only a couple of years due to the increase in efficiency and throughput.

In order to do analysis on this, we would have to consult with a sister Purina plant in Clinton, IA. They are currently implementing a similar conversion in their plant and should be up and running in the near future. We would be able to see the direct effect of the increase in productivity for this type of dryer and present this to our client for his considerations

Future Tasks

Our final design will entail building and testing a small scale prototype of a natural gas drying system. We will compare this to the data collected during our engineering analysis for the existing steam coils. Through this comparison, we intend to prove the increased efficiency of the natural gas drying system. The steam coils may be a cheap solution to the problem that Nestle Purina is experiencing, but this is not a viable long term solution, which is what our client needs. Next semester, we hope to build and test this natural gas prototype to prove that this system has an increased efficiency, and relate this efficiency to a tangible payback period that meets our requirement of 8 years or less.

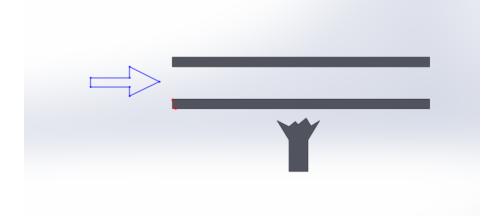

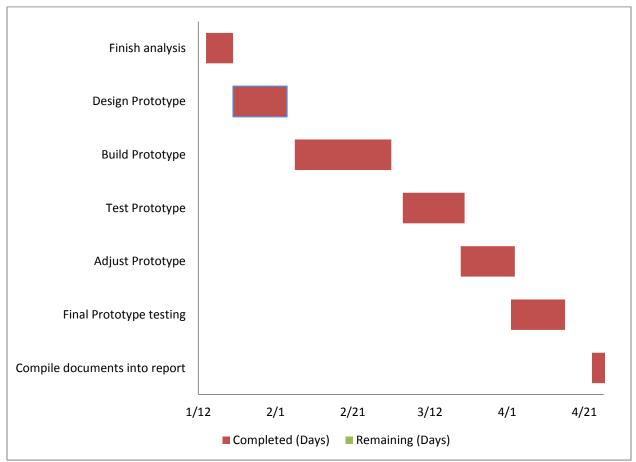

Figure 10 - Natural Gas Model

Figure 1 shows the model for the natural gas fire dryer. The fire underneath the bottom plate will heat the plate. Air flow is represented by the blue arrow, and will flow over the plate, and then flow over the product. The natural gas fire in conjunction with the air flow will replace the steam coils in the current design. The efficiency increase that we expect from this design comes from two sources. The first is the raw efficiency of heat transfer that we will experience using a different heat source. We will measure this by comparing the inlet and exit temperatures of the air. Then we will take into account the cost of the fuel required to heat the air by this amount. The second source of efficiency upgrade will be from the transmission costs of steam. In the plant, steam is currently produced in the boiler, and then travels approximately 300 feet to reach the dryer. By piping the natural gas directly to the dryer, we are able to cut down on the approximate 15% loss that is a direct result of transporting the steam to the dryer. In our future design, we will take into consideration the loss represented by this transport of steam, as well as the temperature difference compared to fuel costs. This is the strategy we will employ when attempting to prove to our client that a natural gas fire system will increase efficiency. In addition, we will complete the cost analysis based on our found efficiency upgrade, and will present to our client the expected payback period when implementing our system.

We hope to implement a low cost prototype to function as a proof of concept for our client. Once we have proved that the natural gas conversion will increase the efficiency of the dryer significantly, we will be able to justify the creation of a more expensive and accurate prototype. This is the end result that we will wish to present to our client.

Project Plan

Figure 11 – Gantt Chart for spring semester.

Conclusion

Dryer 3 having efficiency problems, we decided to fix this with two design solutions. The first is to fix the steam coils, and the second is to convert the system to natural gas. After performing thermodynamic analysis on the steam coils and comparing this to natural gas conversion, we decided to implement a natural gas conversion system for dryer 3. This is a more expensive solution, but in the long term, it will produce more revenue for our client than the steam coil solution. After analysis of the prototype models, we will prove that the natural gas conversion is the correct solution for our client. We will provide the client with a proposal and will await approval for the design as this is a high cost solution. To implement and design an actual natural gas system for a multi-million dollar system is beyond the scope of this class. Therefore, the final product of this class will be to prove the efficiency of a natural gas fire system through the implementation of the prototypes mentioned previously.
